

Employment from the BLS household and payroll surveys: summary of recent trends

Overview

The Bureau of Labor Statistics (BLS) has two monthly surveys that measure employment levels and trends: the Current Population Survey (CPS), also known as the household survey, and the Current Employment Statistics (CES) survey, also known as the payroll or establishment survey.

Estimates from both surveys are published in the “Employment Situation” news release each month. The household and payroll surveys use different definitions of employment and distinct survey and estimation methods. To help data users better understand the differences in the surveys’ employment measures and divergences that sometimes occur in their trends, the following information is provided.

- **Summary comparison of household and payroll survey concepts, definitions, and methodologies**
- **Employment trends as measured by the payroll and household surveys**
- **Possible causes of differences in employment trends**
- **Summary of recent changes made to each survey:**
 - **Population control adjustments to the household survey**
 - **Benchmark revisions to the payroll survey**

Summary comparison of household and payroll survey concepts, definitions, and methodologies

Major features and distinctions of the two surveys are compared below in Box 1.

Box 1. How the household and payroll surveys compare

Comparison by:	Household Survey (CPS)	Payroll Survey (CES)
Universe	Civilian noninstitutional population age 16 and over	Nonfarm wage and salary jobs
Type of survey	Monthly sample survey of approximately 60,000 households	Monthly sample survey of about 160,000 businesses and government agencies covering approximately 400,000 establishments
Major outputs	Labor force, employment, unemployment, and associated rates with significant demographic detail	Employment, hours, and earnings with significant industry and geographic detail
Reference period	Calendar week that includes the 12 th of the month	Employer pay period that includes the 12 th of the month (could be weekly, biweekly, monthly or other)
Employment concept	Estimate of employed persons (multiple jobholders are counted only once)	Estimate of jobs (multiple jobholders counted for each nonfarm payroll job)
Employment definition differences	Includes the unincorporated self employed, unpaid family workers, agriculture and related workers, private household workers, and workers absent without pay	Excludes all of the groups listed at left, except for the logging component of agriculture and related industries

Continued on next page

Comparison by:	Household Survey (CPS)	Payroll Survey (CES)
Size of over-the-month change in employment required for a statistically significant movement	$\pm 436,000^1$	$\pm 103,000$
Benchmark adjustments to survey results	No direct benchmark for employment. Adjustments to underlying population base revised annually to intercensal estimates, and every 10 years to the decennial census	Employment benchmarked annually to employment counts derived primarily from Unemployment Insurance (UI) tax records

¹ This figure is updated periodically to incorporate more current data. The latest update (in March 2005) also included a correction in the program used to calculate it. For more information, see “Updates and adjustments to Current Population Survey standard errors” at http://www.bls.gov/cps/cps_err_update.htm.

Employment trends as measured by the household and payroll surveys

Chart 1 shows employment from the household and payroll surveys from January 1994 through the most recent month. Two variations of household survey employment used in BLS research are presented (these variations differ from the official series that appears in the “Employment Situation” and in the public database available through the BLS website). The green household survey line represents a version of total household survey employment where the effects of sizeable population control revisions in January 2000, 2003, and 2004 have been smoothed. The red “adjusted” household survey line represents the smoothed household survey employment series that has been further modified to make it more similar in concept and definition to payroll survey employment. This adjustment to household survey employment subtracts from total employment agriculture and related employment, nonagricultural self employed, unpaid family and private household workers, and workers absent without pay from their jobs, and then adds nonagricultural wage and salary multiple jobholders.

Chart 1 shows that, because of its broader employment definition, the household survey employment level (green line) normally exceeds that of the payroll survey. When the household survey is adjusted to more closely match the payroll survey definition (red line), trend discrepancies between the two surveys are more discernible. In particular, there is an obvious multi-year period from the late 1990s until the onset of the 2001 recession when payroll employment was growing significantly faster than household survey employment. More recently, the two series converged.

Chart 1. Household and payroll survey employment, seasonally adjusted, 1994-2005

NOTE: The household series presented here has been smoothed for population control revisions. The "adjusted" household series has been smoothed for population control revisions and adjusted to an employment concept more similar to the payroll survey. Shaded area indicates recession.

SOURCE: Bureau of Labor Statistics, October 7, 2005.

Chart 2 shows the same payroll and household employment series as chart 1, but highlights only the 2001 recession and post-recessionary period from March 2001 through the most recent month. The Business Cycle Dating Committee of the National Bureau of Economic Research (NBER) designated March 2001 as the most recent business cycle peak and November 2001 as the most recent trough. (The NBER is a private, nonprofit, nonpartisan research organization that is the generally acknowledged arbiter of business cycle dating.)

From chart 2, more recent trends in employment from the two surveys can be seen. Payroll employment declined for a number of months following the end of the recession, while household survey employment trended up. Since fall 2003, employment as measured by both surveys has trended upward.

Chart 2. Household and payroll survey employment, seasonally adjusted, March 2001-September 2005

NOTE: The household series presented here has been smoothed for population control revisions. The "adjusted" household series has been smoothed for population control revisions and adjusted to an employment concept more similar to the payroll survey. Shaded area indicates recession.

SOURCE: Bureau of Labor Statistics, October 7, 2005.

Box 2 shows the change in employment levels from the payroll and household surveys as measured across the following time periods: 1) over the most recent month, 2) over the most recent year, 3) since March 2001, the most recent business cycle peak, and 4) since November 2001, the most recent business cycle trough. The peak and trough dates are determined by the National Bureau of Economic Research (NBER).

Box 2. Recent trends in payroll and household survey employment

Numbers in thousands

	Over-the-month change: August 2005- September 2005	Over-the-year change: September 2004- September 2005	From March 2001 (peak)- September 2005	From November 2001 (trough)- September 2005
Payroll survey: total nonfarm employment, seasonally adjusted ¹	-35	2,161	1,530	3,162
Household survey: total employment, smoothed for population control revisions and seasonally adjusted	-17	2,905	4,519	6,028
Difference	18	744	2,989	2,866

¹ Payroll employment for September 2005 is preliminary and subject to revision.

NOTE: The household survey figures in Box 2 are calculated from a variation of household survey employment used in BLS research (also shown by the green lines in Charts 1 and 2). This version of household survey employment smooths out the effects of sizeable population control revisions to the survey in January 2003 and January 2004.

Box 3 shows employment trends in the payroll and household surveys over the same periods as in Box 2, but this illustration uses adjusted household employment that is more comparable to the payroll survey (also shown in Charts 1 and 2). Even with this adjustment, the difference in employment change as measured by the two surveys since March or November of 2001 is significant.

Box 3. Recent trends in payroll employment and household survey employment adjusted to an employment concept more similar to that of the payroll survey

Numbers in thousands

	Over-the-month change: August 2005- September 2005	Over-the-year change: September 2004- September 2005	From March 2001 (peak)- September 2005	From November 2001 (trough)- September 2005
Payroll survey: total nonfarm employment, seasonally adjusted ¹	-35	2,161	1,530	3,162
Household survey: total employment, smoothed for population control revisions, adjusted to be more like the payroll survey, and seasonally adjusted	227	2,984	5,095	6,356
Difference	262	823	3,565	3,194

¹ Payroll employment for September 2005 is preliminary and subject to revision.

NOTE: The household survey figures in Box 3 are calculated from a variation of household employment used in BLS research (also shown by the red lines in Charts 1 and 2). This version of household employment smooths out the effects of sizeable population control revisions to the survey in January 2003 and January 2004. In addition, it adjusts household survey employment to make it more similar in concept and definition to payroll employment. This adjustment to household survey employment subtracts from total employment agriculture and related employment, nonagricultural self employed, unpaid family and private household workers, and workers on unpaid leave from their jobs, and then adds nonagricultural wage and salary multiple jobholders.

Possible causes of differences in employment trends

The following summarizes some issues with the surveys that are important when comparing changes in employment from the two sources.

Sampling error – The payroll survey has a much larger sample size than the household survey. The payroll survey’s active sample covers approximately 400,000 business establishments *of all sizes* representing about one-third of total nonfarm employment. The household survey is much smaller at 60,000 households, covering a very small fraction of total employed persons. Household survey employment is therefore subject to larger sampling error, about 4 times that of the payroll survey on a monthly basis (see Box 1). When looking at short-term trends in either survey, especially over-the-month changes, it is essential to assess the statistical significance of the change. When comparing the two series over longer periods of time, however, other factors also need to be considered; some of these are discussed below.

Payroll survey benchmark – The payroll survey estimates are benchmarked once a year against a full universe count of employment derived from Unemployment Insurance (UI) tax records that nearly all employers are required to file. The payroll survey’s latest benchmark—to March 2004 employment records—resulted in an upward revision of 203,000 (156,000 on a seasonally adjusted basis) or two-tenths of one percent. The historical average for benchmark revisions over the past decade has been plus or minus two-tenths of one percent. Hence, payroll employment continues to track closely with the universe of nonfarm payroll employment.

With regard to the benchmark source data, BLS has reviewed information from publicly available UI management reports concerning the timeliness of new business enrollments into the UI system. The findings are available in the report “Assessing the Timeliness of Business Births in BLS Establishment Statistics” on the BLS Internet site at <http://www.bls.gov/cew/eta581study.pdf>.

New business births in the payroll survey – The payroll survey sample does not include new firms immediately. They are incorporated with a lag. In the interim, a model-based estimate is used each month to account for employment resulting from new firm births. Based on the relatively small benchmark revision for March 2004, the model appears to be performing well during the recent period. Additional information about the birth/death model used in the payroll survey estimates is on the BLS Internet site at <http://www.bls.gov/web/cesbd.htm>.

Job changing - Employment estimates from the payroll survey are a count of jobs, unlike the household survey which provides a count of employed persons. If a person changes jobs within a payroll survey reference period, which is defined as the pay period including the 12th of the month, both jobs will be counted by the payroll survey estimates. If the rate of job-to-job movement changes substantially over time, it could impact trends produced from the payroll survey. While there is no method to directly measure effects from job changing, BLS is researching this issue using job change rates from the household survey. The initial findings of this research are provided in the report “Effects of Job Changing on Payroll Survey Employment Trends” at <http://www.bls.gov/ces/cesjobch.pdf>.

Population controls in the household survey – Population controls determine the weights used in the household survey to adjust the sample results to the overall level of the U.S. population. The population controls are developed by the U.S. Census Bureau. They are derived from decennial census information and, between census years, from administrative and other data. There are limitations to the population control estimates due primarily to the difficulties associated with estimating the net international migration component. The population controls contributed significantly to the discrepancy between payroll and household survey employment in the 1980s and 1990s when the household survey showed less growth than the payroll survey.

Worker classification in the household survey – As was illustrated in Box 3 above, adjusting for the measurable differences in the surveys' employment definitions resolves only a portion of the discrepancy. This adjustment process is imperfect, however, because precise data are not available in many cases to make the best possible adjustment. For example, some independent contractors are not reported as self employed in the household survey, but rather as wage and salary workers. This type of reporting issue limits BLS' ability to fully reconcile the two employment measures.

“Off-the-books” employment – Workers who are paid “off-the-books” are not reported in the payroll survey. The household survey could possibly include some of these workers, but BLS cannot determine the extent to which they might be reflected in household survey employment.

Summary

- BLS has estimated the measurable definitional differences between the household and payroll surveys and found they provide a partial explanation for the employment trend differences. There are a number of definitional differences between the surveys that cannot be readily measured or quantified. These differences may contribute to divergences in the surveys' trends, but their effects are either unknown or can only be conjectured. In addition, although BLS has devoted considerable attention to this issue, there may be other contributing factors that have not been identified.
- A summary of some of BLS' research was presented to the Federal Economic Statistics Advisory Committee (FESAC) in October 2003. The paper is available on the BLS Internet site at <http://www.bls.gov/bls/fesacp2101703.pdf>.
- BLS is continuing to investigate possible causes of recent divergences in employment growth between the payroll and household surveys. BLS also has implemented improvements that addressed past limitations. The redesign of the payroll survey, for example, led to the use of a probability sample, more frequent updating of the survey sample frame, and the development of a more effective means to estimate business births and deaths. With regard to the household survey population controls, the Census Bureau remains engaged in efforts to improve the intercensal population estimates. In particular, they have begun utilizing information from the large American Community Survey (ACS) to improve the estimates of net international migration.
- Both the payroll and household surveys are needed for a complete picture of the labor market. The payroll survey provides a highly reliable gauge of monthly change in nonfarm wage and salary employment. The survey has a large probability sample, and is benchmarked annually to a universe count of jobs derived from the unemployment insurance tax system. The payroll survey offers industry and geographic information at very detailed levels. The household survey provides a

broader picture of employment including agriculture and the self employed, as well as detailed information on the demographic composition of the employed and the unemployed.

Population control adjustments to the household survey

January 2005 adjustment – As part of its annual review of intercensal population estimates, the U.S. Census Bureau determined that a small downward adjustment should be made to the household survey population controls. This adjustment stemmed from revised estimates of net international migration for 2000 through 2004 and updated information on births and deaths. In keeping with usual practice, the new controls were used in the survey starting with data for January 2005. Estimates for December 2004 and earlier months were *not* revised to reflect the new population controls.

A comparison of December 2004 data based on the old and new controls indicated that the revision to the population controls had little effect on the estimates of the labor force (-49,000), employment (-45,000), and unemployment (-4,000). The total unemployment rate, labor force participation rate, and employment-population ratio were not affected. Additional details on the January 2005 population adjustments are provided in the table below.

January 2005 household survey population control adjustment effect

Employment status of the population, December 2004, not seasonally adjusted

(Numbers in thousands)

	December 2004 as published	December 2004 based on adjusted population controls	Difference ¹
Civilian noninstitutional population	224,640	224,632	-8
Civilian labor force	147,877	147,828	-49
Participation rate	65.8	65.8	.0
Employed	140,278	140,233	-45
Employment-population ratio	62.4	62.4	.0
Unemployed	7,599	7,595	-4
Unemployment rate	5.1	5.1	.0
Not in labor force	76,763	76,804	42

¹ Differences are calculated from unrounded estimates.

Previous population control adjustments – The 2005 population control adjustment followed a larger *decrease* in the controls and two previous *increases* in the controls.

With the release of January 2003 household survey data, BLS introduced two separate adjustments that increased the survey population controls.

- 1) Beginning in January 2000, household survey estimates reflect an increase in population resulting from the switch to the Census 2000 population controls.
- 2) In January 2003, household survey estimates reflect new, higher population controls. The upward adjustment resulted from higher estimates of net international migration in the population for 2000 through 2002.

With the release of January 2004 household survey data, BLS introduced adjustments that lowered the population controls. The downward adjustment resulted from lower estimates of net international migration in the population for 2000 through 2003.

These adjustments in population controls resulted in level shifts in the January employment estimates from the household survey in those years. The impact on employment of the January 2000 adjustment was an increase of approximately 1.6 million. The impact of the January 2003 adjustment was an increase of about 576,000. The January 2004 adjustment effect was a decrease of about 409,000.

Interpreting household data with the population control adjustments – The level shifts in household survey employment resulting from these population adjustments make it difficult for data users to compare changes in employment over time periods that include these adjustments. As a convenience to its data users, BLS created a research series that smoothes out the level shifts in employment resulting from the January 2000, 2003, and 2004 population control adjustments over a multi-year period rather than incorporating the entire changes in January of the years that they were implemented. Because the effects of the January 2005 adjustments were so small, especially when spread over a multi-year period, BLS did not incorporate them into the smoothed research series.

This household employment research series was used in Charts 1 and 2 and Box 2 above to provide a clearer picture for analysis. The full series, 1990-2003, is shown in the table below. Users should be aware that this research series will not match the official estimates in BLS publications and on the BLS website.

**Household Survey Employment Smoothed for Population Controls, Seasonally Adjusted,
January 1990-December 2003**

2000	128,866	128,949	128,960	130,068	129,220	129,382	129,489	129,515	129,614	130,139	130,104	130,504
2001	130,248	130,240	130,213	129,855	130,097	129,840	130,297	129,639	129,776	129,082	128,952	128,998
2002	128,885	129,776	129,464	129,634	129,539	129,649	129,442	130,321	130,479	129,770	129,152	129,612
2003	129,820	130,038	129,887	130,116	129,964	129,975	129,594	129,745	129,511	129,851	130,018	130,062
2004	130,808	130,729	131,146	131,129	131,427	131,680	132,036	132,038	132,324	132,631	132,749	132,985
2005	132,618	132,567	132,938	133,510	133,757	134,162	134,628	135,081	135,308			

NOTE: This series represents not seasonally adjusted household survey employment that has been revised from January 1990-December 2003 to smooth out the effects of population control revisions introduced in January 2000, 2003, and 2004. The data from 1994 forward were then adjusted to an employment concept more similar to the payroll survey by subtracting from total employment agriculture and related employment, the self employed, unpaid family and private household workers, and workers on unpaid absences and then adding nonagricultural wage and salary multiple jobholders. The resulting employment series was then seasonally adjusted.

Source: Bureau of Labor Statistics, Division of Labor Force Statistics, October 7, 2005

Benchmark revisions to the payroll survey

Benchmark revisions are a standard part of the payroll survey estimation process. The benchmark adjustment represents a once-a-year re-anchoring of sample-based employment estimates to full employment counts available through unemployment insurance (UI) tax records filed by nearly all employers with State Employment Security Agencies.

The incorporation of March 2004 benchmarks published on February 4, 2005, led to a revision of all not seasonally adjusted data for the period subsequent to the last benchmark; that is, for April 2003 forward. At the same time, seasonally adjusted employment, hours, and earnings series were revised from January 2000 forward to incorporate updated seasonal adjustment factors.

March 2004 Benchmark Effects on the Nonfarm Payroll Series

The total nonfarm employment level for March 2004 was revised upward by 203,000 (156,000 on a seasonally adjusted basis) or two-tenths of one percent. Over the past 10 years, benchmark revisions have averaged 0.2 percent with a range from near zero to ± 0.5 percent.

Following standard BLS methodology, estimates were recalculated for the year preceding and the months following the March 2004 benchmark reference month. The March 2004 UI-based benchmark level replaced the March 2004 sample-based employment estimate. The difference between the benchmark level and the estimate was wedged back to the previous benchmark level: 1/12 of the difference was added to the April 2003 employment level, 2/12 to May 2003 and so forth, through February 2004, which received 11/12 of the difference.

Estimates for April 2004 forward were recalculated by applying over-the-month changes from the sample to the new benchmark level, along with recomputed net birth/death factors, and new seasonal adjustment factors.

Revisions for November 2004 result from the effects of the benchmark process described above and the routine incorporation of additional sample receipts into the final estimates.

The net impact of the benchmarking process for January 2004 through November 2004 is shown in the table below.

Revisions in total nonfarm employment, seasonally adjusted, in thousands

	Employment levels			Over-the-month changes		
	Employment levels as previously published	Employment levels as revised		Over-the-month changes as previously published	Over-the-month changes as revised	Difference
2004						
January	130,194	130,372		159	117	-42
February	130,277	130,466		83	94	11
March	130,630	130,786		353	320	-33
April	130,954	131,123		324	337	13
May	131,162	131,373		208	250	42
June	131,258	131,479		96	106	10
July	131,343	131,562		85	83	-2
August	131,541	131,750		198	188	-10
September	131,660	131,880		119	130	11
October	131,972	132,162		312	282	-30
November	132,109	132,294		137	132	-5
